This checklist is automatically generated using Version 3.0 of the online database CDF Galapagos Species Checklist.

Basidiomycetes are fungi that reproduce by forming spores via specialized club-shaped end cells called basidia.

Well known macro-fungi (mushrooms, puffballs, stinkhorns, bracket fungi, jelly fungi, boletes, and chanterelles) belong to this group of organisms, other less known basidiomycetes are smuts and rusts.

Very few basidiomycetes form lichens. This checklist of known basidiomycetes from the Galapagos Islands is currently based on the sparse literature records available and a few recent field surveys on the central island of Santa Cruz. These few records are by no means comprehensive and it is estimated that the current list represents less than 80% of the diversity of Galapagos Basidiomycota.

For marine species distribution data cited in the CDF Galapagos Checklists refer to the five main bioregions of the archipelago (Far Northern, Northern, Western, South Eastern and the Elithabeth Bay Bioregion). For the terrestrial species the more than 120 islands, islets and small rocks have been aggregated into Islands Groups, thus, for example, the island group "Santa Cruz" includes smaller islands like Santa Fé, Plaza Norte, Plaza Sur, Baltra, Daphne Mayor, Daphne Minor, and others.

Please be aware that the distribution data presented here is automatically generated from specimen records and does not always accurately reflect the known distribution for all species.

IUCN red-list assessments presented here may deviate from the global IUCN list for the following reasons:

- for well known species groups like vascular plants or vertebrates updates proposed to the IUCN are shown instead of the outdated, but currently accepted status;
- for poorly known species groups (e.g., lichenized fungi) a general assessment is currently not possible and the list presented here is a regional red-list list for Galapagos archipelago.
